## Executive Summary

The site, which was formerly a large open cast sand/gravel pit, comprises an area of virgin land where the former works buildings were situated and an area of land which was infilled after quarrying. At the time of our investigation the site comprised a disused former Outdoor Centre, which contained numerous derelict buildings and large areas of car park. The open land to the south and east of these buildings comprised overgrown open land with mixed self-sown shrubs and trees along with small areas of woodland and small ponds. In the centre of the site, to the southeast of the main building, a large raised soil mound, approximately 2-4m in height is situated. Adjacent to the soil mound were further old derelict buildings and what appears to be an old landing stage onto the lake.

The lake covers the majority of the site, and was observed to be relatively still and clean, with clear water observed on the edges of the lake where access was available. The base of the lake appeared to be made up of sand and gravel based soils.

The site is mapped as being situated directly on Peat overlying River Terrace Gravels, which overlie the bedrock geology of Ampthill Clay. It is understood that the Peat has been removed and that large scale excavation of sand and gravel has taken place. Areas of the site where the former works buildings are situated are likely to comprise the natural soil profile, areas to the south where the land has been infilled is likely to comprise highly variable made ground.

A total of seven trial pits were excavated across the site at locations within the proposed burial area. The soils encountered on site were found to comprise highly variable made ground soils comprising loose, poorly compacted sand, made ground and pockets of demolition rubble potentially including asbestos containing materials. Further assessment should be undertaken to assess the nature of the made ground and potential for contamination to be encountered across the site.

Groundwater was only encountered in a single trial pit, TP106 at a depth of 2.0m bgl. The remainder of the trial pits, situated on slightly higher ground, were found to be dry to depths of upto 3.3m bgl. Groundwater monitoring wells installed across the site have identified a consistent groundwater table across the site at depths of approximately 2.8m to 3.5m bgl.

Based on the nature of the soils encountered and the observed trench instability, we would recommend that burials be restricted to single depth burials only due to the significant risks associated with large scale side wall collapse. Single depth burials would provide the required 1m unsaturated zone beneath the base of the burial based on the results of the groundwater monitoring to date.

The site is not considered to be situated in a sensitive groundwater area, with no groundwater source protection zones mapped on site and no potable abstraction wells mapped within 1 km of the site. In terms of receptors, the nearest would be the lake to the west and the east, which may have ecological value and could be impacted by changes in water quality associated with burial contaminants such as nitrates and ammonia as it is likely to be in hydraulic continuity with water below the site. The freely draining nature of the soils offers little in the way of protection to this source.

Given the above, the presence of proposed future burials does provide a source of potential pollutants, such as ammonia, nitrate, formaldehyde and bacterial contaminants, which could have a significant impact on the water quality beneath the site and in the lake to the west and to the east.

Consideration should be given to undertaking pollutant flux modelling to assess the impact burials would have on the water quality of adjacent surface water features and the underlying groundwater.

## 1 Introduction and Site Location

The CDS Group have been asked to carry out a Tier 2 groundwater risk assessment for new cemetery. This site will be considered on the basis of groundwater risk and as part of this, a T2 study based on the criteria required by the Environment Agency has been carried out. This is because sites that do not meet the requirements of the Environment Agency should be ruled out at an early stage since the Agency as Primary Consultees are able to prevent any site being developed should the site be deemed to represent too great a risk in respect to water pollution.

The proposed development area has been assessed on a 1km area of influence: Easting and Northings: 542308, 282928 and the nearest postcode is CB6 2BA. The total site area is approximately 13.1 hectares (red line boundary), however the burial area (blue line boundary) is approximately 2.0 hectares.

Figure 1. OS map of the site (boundary indicated in red)

Figure 2. Aerial Image of the site (boundary indicated in red)

This report will review the site proposed for use as a green burial facility (woodland burials only) in accordance with the requirements of the Environment Agency's Tier 2 survey. The exact burial number for this site is currently unknown, however we understand burial numbers have been anticipated to be less than 30 per annum.

## 2 Background

This section sets out the relevant legal and policy advice relevant to the grant of planning permission for new and also the operation of existing cemeteries. New cemetery developments or extensions to existing cemeteries can be very emotive. However, these concerns are often disproportionate to the actual environmental risk.

Whilst the Local Planning Authority is the principal controlling body in determining approval for new sites or site extensions, significant information is required to ensure that the environmental risks are examined and that the Environment Agency's views are considered. Therefore, measures to prevent

pollution must be undertaken and reported. Any regulatory decision-making is based on sound scientific knowledge. On this basis, a review of potential pollution from cemeteries was undertaken by the Environment Agency in collaboration with the British Geological Survey.

The aim was to review old and new cemeteries and measure the effects of contamination from viruses, bacteria and other microbiological pathogens and to assess the potential of chemical contaminants affecting groundwater supplies from decomposition processes. Preliminary results showed that the operating cemetery examined in the study (25 years old) did show some evidence of bacterial contaminants in groundwater derived from corpses. However, no viruses were detected and the overall contaminant loading was found to be low. The studies found that degradation and attenuation was occurring indicating that potential risks were low. Whilst the outcome of this research found contaminant risk to be low, it should be reviewed in the context that natural attenuation processes may have been optimum at these sites. Therefore, to optimise natural attenuation and reduce the risk of possible groundwater contamination, a series of guidelines have been drawn up that are directly applicable to cemeteries.

The most up-to-date guidance issued by the Environment Agency is provided in:

- 'The Environment Agency's approach to groundwater protection' (February 2018 Version 1.2), which updated 'Groundwater protection: Principles and practice (GP3) (2013)'; and
- 'Cemeteries and burials: prevent groundwater pollution' which was published in March 2017 and updated in February 2018. The purpose of the guidance is to help those operating cemeteries to understand how to manage cemeteries and burial of human and animal remains, to prevent or limit groundwater pollution.

Failure to manage and reduce any environmental risk to a minimum may result in action being taken under the Environmental Permitting (England and Wales) Regulations 2016, the Water Resources Act 1991 and the Anti-pollution Works Notice Regulations 1999.

## **2.1 Groundwater Protection Policy**

Initial risk screening starts with the tools contained in the 'The Environment Agency's approach to groundwater protection' (previously Principles and Practice for the groundwater protection), Section L: Cemetery developments GP3.

Tools include Groundwater Vulnerability and Source Protection Zone (SPZs) maps. These maps highlight where there are likely to be particular risks posed to groundwater from surface activities. Groundwater Vulnerability (GWV) Maps show the damage from pollution to groundwater and the relative importance of the aquifer to water supplies. Risk assessment is made with reference to soil leaching potential and the levels of water tables above major and minor aquifers.

Source Protection Zones are delineated areas around groundwater abstractions used for public consumption and defined by travel, time of biological or chemical contaminants.

The zones are classified in three groups:

- Zone 1 High risk**
- Zone 2 Intermediate to high risk**
- Zone 3 Intermediate risk**

In its Position Statement L1 (p109 of 'The Environment Agency's approach to groundwater protection') the Agency advises that it will object to the grant of planning permission for any new cemetery, or the

extension of an existing cemetery, within Zone 1 of an SPZ or 250 metres from a well, borehole or spring used to supply water that is used for human consumption, whichever is the greater distance. Position Statement L3 advises on the protection of groundwater in highly sensitive locations. The Agency advises that it will apply a risk-based approach to assessing the suitability of sites outside of the zones noted in position statements L1 and L2 (concerning mass casualty emergencies). It will place a high priority on protecting groundwater within principal aquifers and groundwater catchments for drinking water supply; and seek to avoid new cemetery developments for greater than 100 graves in these high vulnerability areas except where the thickness and nature of the unsaturated zone, or the impermeable formations beneath the site protect groundwater, or the long-term risk is mitigated by appropriate engineering methods. It advises that all cemetery developments and burials must maintain an unsaturated zone below the level of the base of the grave(s) and that the Agency will work with the local authorities to identify alternative options where necessary. Whilst groundwater is a major part of policy concerns, other water point sources are also considered as requiring an evaluation of risk. These sources include surface water in the form of ditches, spring lines and surface run-off.

The factors influencing the risk of groundwater vulnerability include:

- Soil nature and type
  - Physical, mechanical and chemical properties
- Geomorphology
  - Depth to water table and or height above aquifers
  - Groundwater flow mechanisms
  - Aquifer type
- Abstractions
- SPZs
- Proximity to water courses, ditches and drains

Therefore, prior to any consent being given by the Environment Agency, an assessment of risk should be undertaken. The degree of assessment is measured through a series of stages namely:

- Hazard identification
- Identification of consequences
- Magnitude of consequences
- Probability of consequences
- Significance of risk

## 2.2 Tiered risk assessment

There are 3 Tiers of Risk assessment. The associated size and position of the site will in-part determine which Tier is appropriate.

### Tier 1

Desktop study of all appropriate documentation including GWV and SPZ maps, topographical, hydrological and geomorphologic maps. After adopting a systematic approach to the assessment of risk, a weighting can be given which is assessed as low, medium or high. If the overall risk is low, the proposal may be accepted by the Agency without further detailed assessment. However, the following practical guidelines would be recommended as appropriate controls to minimise pollution risk:

- 250 m distance from groundwater supply
- 30 m minimum distance from a watercourse or spring

- 10 m distance from field drains
- No burials in standing water

#### Tier 2

Should the risks not be clearly defined by the Tier 1 desktop study then further “ground truthing” might need to be undertaken. This will include the excavation of trial pits or boreholes on site to assess the nature of the ground conditions on site and whether either perched water or groundwater is encountered.

On further assessment of the ground model the risk assessment for the site can be re-assessed which may indicate the requirement for a pollutant flux model to be carried out to assess the impact of the modelled pollutants on the underlying groundwater and nearest compliance point.

#### Tier 3

If the risk is considered high, i.e. the number of yearly burials exceeds 1,000; a full groundwater audit will be required. This would include, but not be limited to, a detailed site investigation including installation of a minimum number of three boreholes, back groundwater quality analysis and ongoing monthly monitoring and sampling.

### **2.3 Water Resources Act 1991 – S161A Anti-Pollution Works Notices**

The EA has powers under s161A of the Water Resources Act 1991 and the Anti-Pollution Works Regulations 1999, allowing Works Notices to be served to require specified steps to be taken to prevent or remedy pollution of controlled waters.

### **2.4 Environmental Permitting (England & Wales) Regulations 2016**

Burial of human corpses can result in discharge of hazardous substances and non-hazardous pollutants to groundwater. They are, therefore, covered by the requirements of the EU Groundwater Daughter Directive, issued under the Water Framework Directive 2006 and now transposed in England and Wales by the Environmental Permitting (England & Wales) Regulations 2016 (EPR 2016). It is an offence to cause or knowingly permit pollution of controlled waters other than under and in accordance with an environmental permit.

---

## **3 Site Assessment**

Envirocheck, British Geological Survey and Cranfield University data was used in this report.

### **3.1 Historical Land Use**

The site is first shown on the 1887 historical map as a series of open fields with ditch lines shown running broadly east to west. The site is bounded by fields in all directions, and Iretons Road is mapped directly offsite to the east. The site and immediate surrounding area remained essentially unaltered up to the 1927 map. Between the 1927 map and the 1952 map significant change has taken place on site.

The 1952 map shows that the large majority of the site has been excavated as part of a large scale gravel works, a small section of land along the eastern boundary has remained unexcavated, containing several buildings and what appears to be a conveyor belt system. The 1981 map shows that the south eastern corner and the southern part of the site has been backfilled, and a car park has been developed to the south of what appears to be the former works buildings. The land off site to the east

by the 1981 map has also been fully excavated and is now mapped as Mepal Fen, it is likely that this excavation is the source of the material which was used to partially backfill the southern section of the subject site.

By the final map, dated 1990, the southern section of the site, which is now backfilled, is mapped as the Mepal picnic site. The 1999 aerial map shows that the site was later developed into the Mepal Outdoor Centre, with a number of new buildings constructed on what is thought to be natural ground where the former works buildings were situated. The southern infilled section of the site appears to have been developed into a Caravan Club site, with external outbuildings constructed.

### 3.2 Soil Type

According to the Soil Survey of England and Wales, the soils on site are mapped as belonging to the Ireton Soil Association as described in Figure 3 and Table 1. However, the historical map analysis has shown that the land in the southern corner of the site has been infilled and is likely to comprise made ground soils. As such, the soils on site are not considered to be representative of the mapped soil type being more accurately classed as an anthropogenic lithomorphic soil.

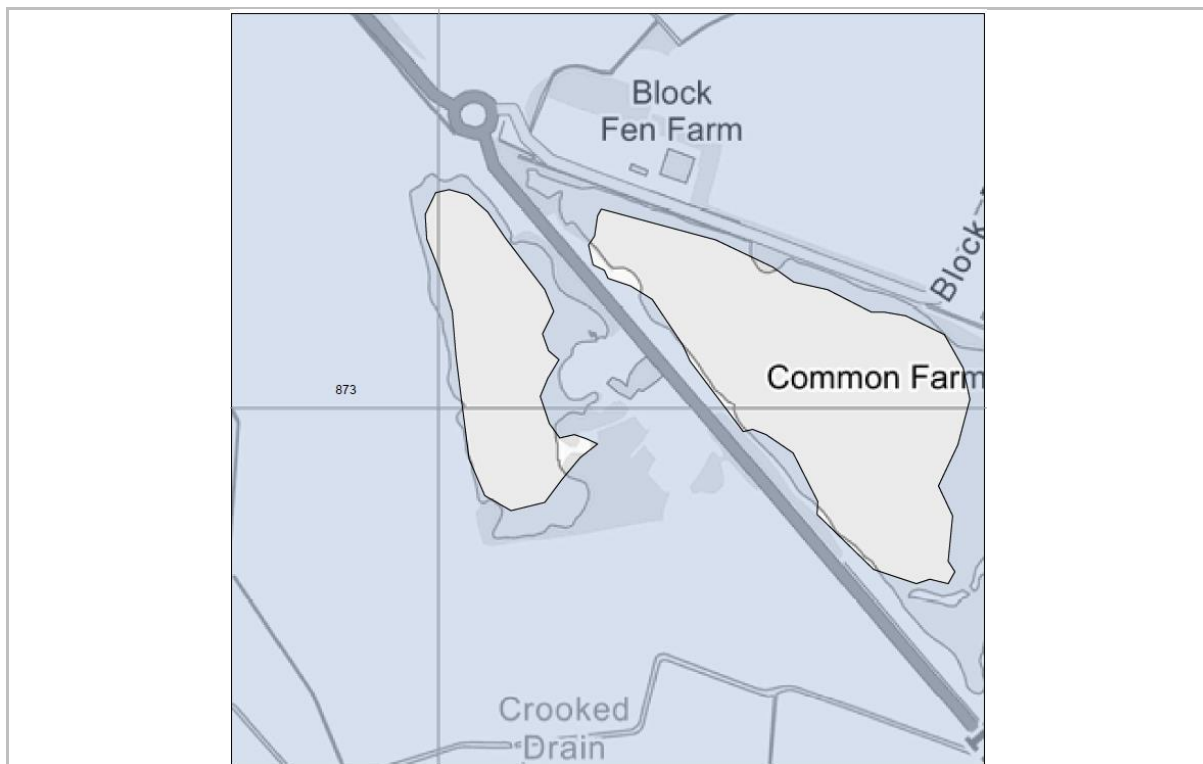

Figure 3. Soil Associations in the vicinity of the site.

Table 1. Soil Associations in the vicinity of the site

Soil Association	Sub Groups	Description
873	Ireton	Permeable humose coarse and fine loamy soils associated with humose calcareous coarse loamy over sandy soils.

#### Suitability for use as cemeteries:

These soils are likely to be well drained and are suitable for use as surface water flooding issues are unlikely to be encountered. Such soils would however offer little protection to the groundwater from burial contaminants due to the highly permeable nature of the soils, the low cation exchange capacity and the unstable physical characteristics of such soils once excavated.

### 3.3 Geology

The following headings cover the aspects of geology of the immediate area of the proposed development.

#### 3.3.1 Artificial Ground

This is ground at or near the surface that has been modified by man. It includes ground that has been deposited (Made Ground), landscaped, disturbed, excavated (Worked Ground) or some combination of these.

As can be seen in Figure 4, there are no mapped artificial deposits on or in the immediate vicinity of the site. However, the historical map analysis has shown that the land in the southern corner of the site has been infilled and is likely to comprise made ground soils. As such, the made ground soils are likely to be highly variable in composition and likely to be composed of reject sand and gravel from the excavation of the Mepal Fen to the east. Contaminated soils, organic material and rubble are also likely to be found on site.

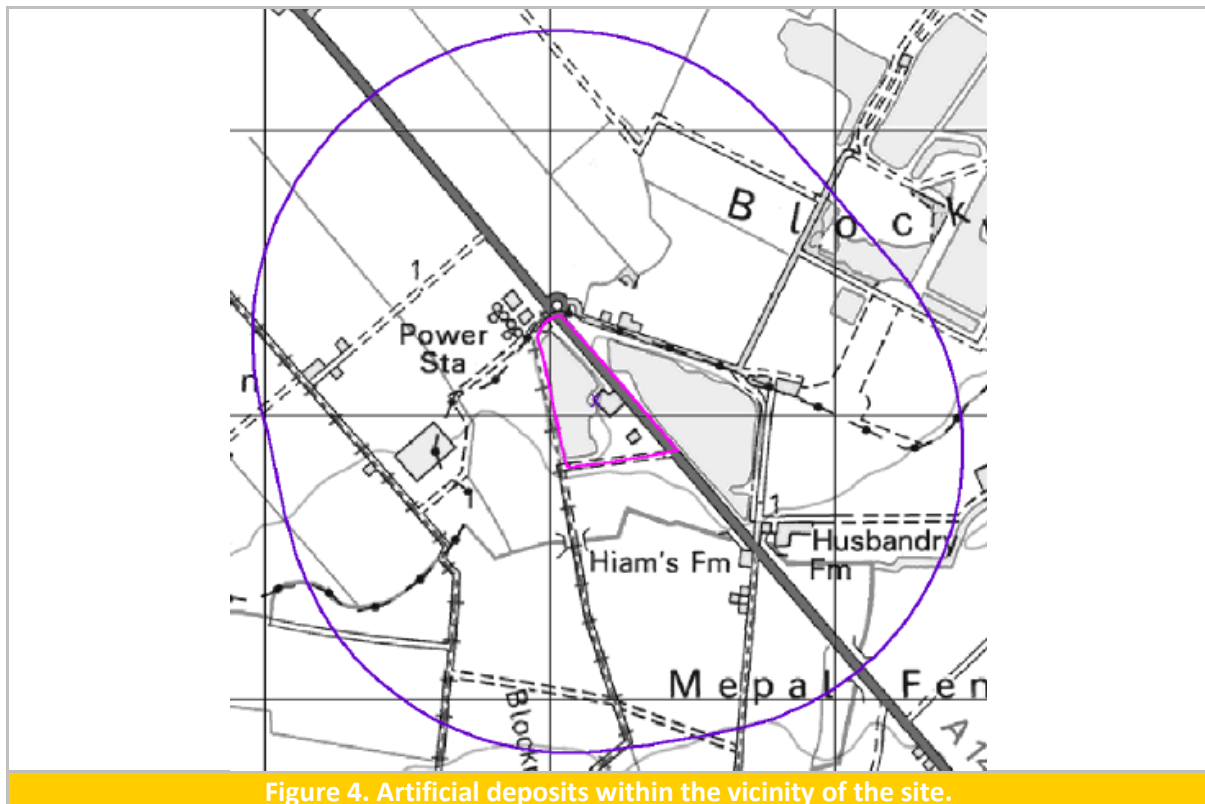

Figure 4. Artificial deposits within the vicinity of the site.

#### 3.3.2 Superficial Deposits

These are relatively young geological deposits formerly known as 'Drift', which lie on the bedrock in many areas. They include deposits such as unconsolidated sands and gravels formed by rivers and clayey tills formed by glacial action. They may be overlain by landslide deposits, by artificial deposits or both (Figure 5).

As can be seen in Figure 5, the superficial deposits are mapped as Peat overlying River Terrace Deposits. The subject site has however been quarried and it is likely that the Peat soils were removed as part of the excavation process and disposed off site. As such the likelihood of encountering Peat soils on site is low, as the quarry was most likely excavated down into the underlying River Terrace Gravels.

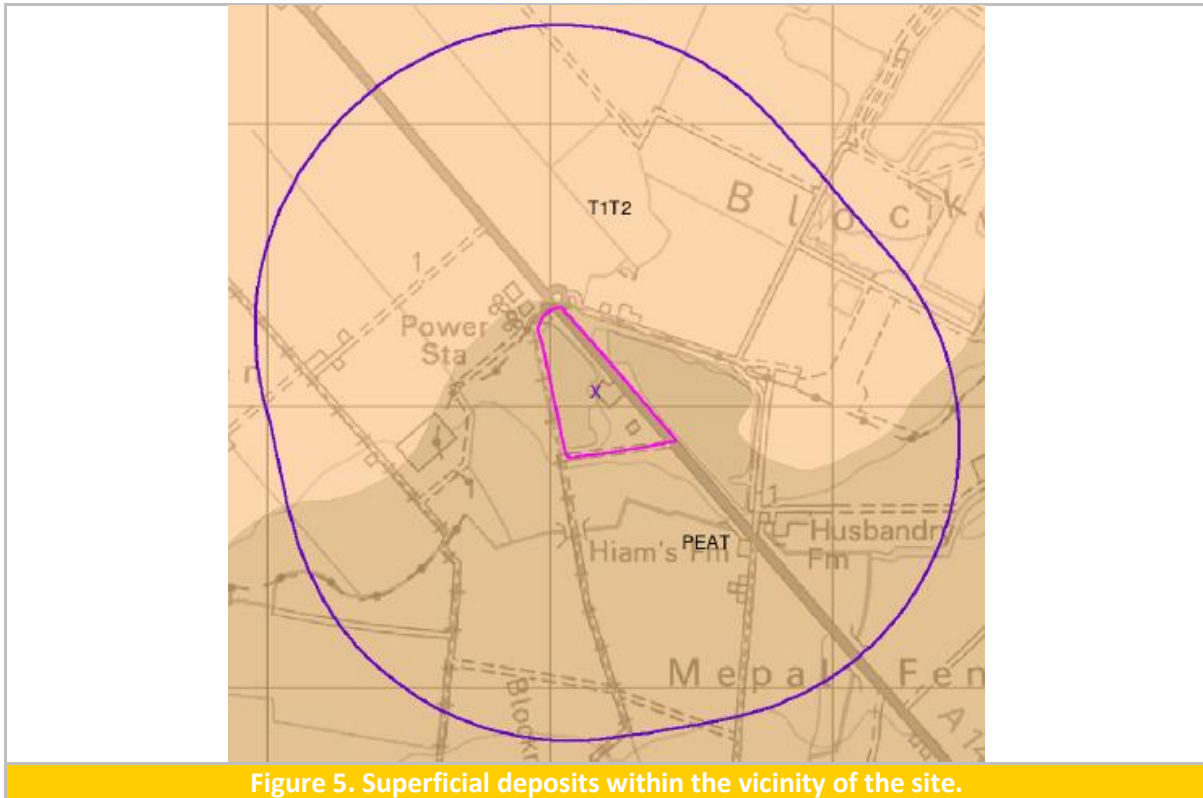

Figure 5. Superficial deposits within the vicinity of the site.

### 3.3.3 Rockhead Depth

According to nearby borehole records, the Ampthill Clay Formation is encountered at depths of between 3.2m - 5.3m bgl (TL48SW3, TL48SW2 and TL48SW4) beneath the River Terrace Deposits.

### 3.3.4 Bedrock Geology

Bedrock forms the ground underlying the whole of an area, commonly overlain by superficial deposits, landslide deposits or artificial deposits, in any combination.

As can be seen in Figure 6, the bedrock geology is Ampthill Clay Formation, a mudstone with some argillaceous limestone nodules dating from the Upper Jurassic period.

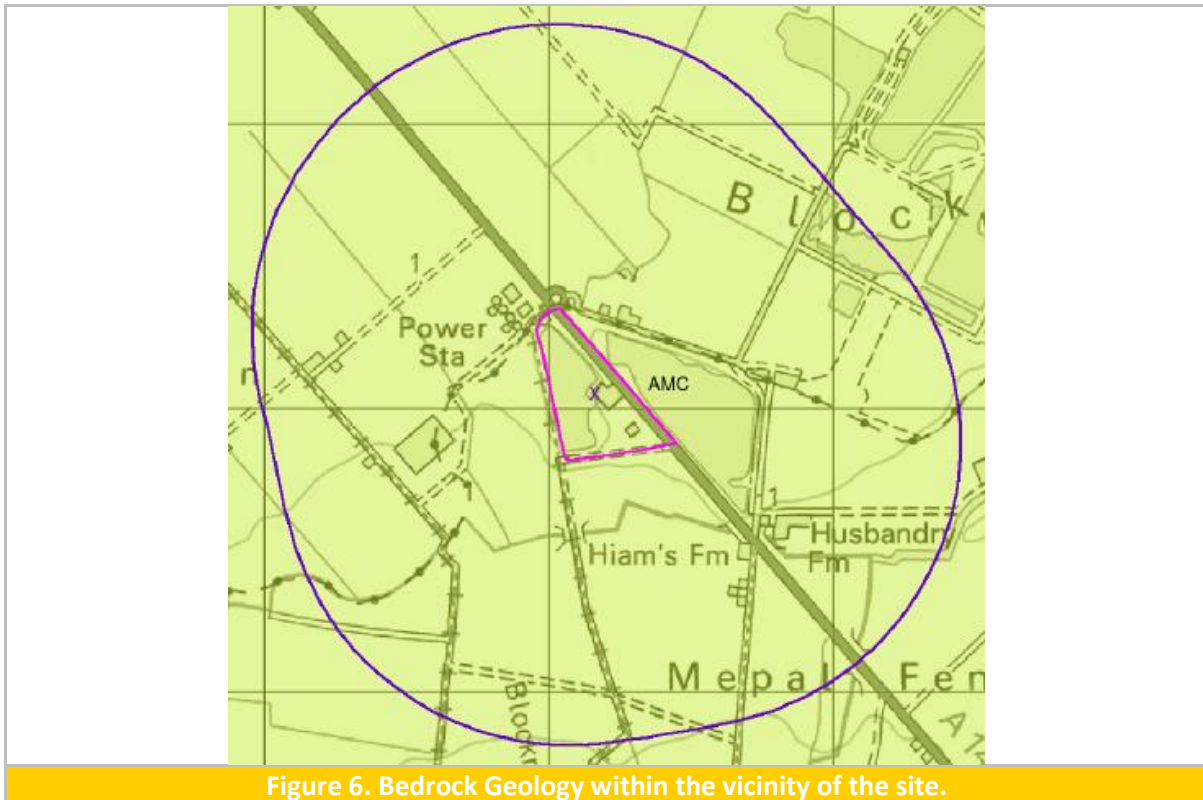

Figure 6. Bedrock Geology within the vicinity of the site.

### 3.4 Additional Geological Considerations

A summary of the potential geological hazards which could be found on site are explained in Table 2 below:

**Table 2. Onsite Geological Hazards**

Geological hazard	May be significant within site area (Yes/No)?	Comments
<b>Potential Natural Ground Stability Hazards</b>		
<b>Shrink-Swell</b>	No	<p>The mapped geology on the site predominantly comprises granular based sand and gravel, which would not be considered at risk of swelling and shrinkage.</p> <p>The made ground soils encountered on site are also likely to be predominantly granular based and would also not be considered to pose a risk.</p>
<b>Landslides (slope instability)</b>	No	<p>The site is predominantly flat and level, and as such the risk of landslip is considered to be low.</p> <p>There are mounds of imported sand based soils across the subject site, ranging from 1m in height upto 3-4m in height. These are not considered an immediate risk but should be assessed during any earthworks.</p>

Geological hazard	May be significant within site area (Yes/No)?	Comments
<b>Soluble Rocks (dissolution)</b>	No	The site is not situated on a geology which is susceptible to dissolution and as such there is no risk.
<b>Compressible Ground</b>	Yes	The site is not situated on a geology which is susceptible to compression and as such there is no risk.  However, the made ground soils encountered on the subject site are likely to be loosely compacted and could be subject to ongoing differential settlement.
<b>Collapsible Deposits</b>	No	The site is not situated on a geology which is susceptible to collapse and as such there is no risk.
<b>Running Sand</b>	Yes	Given that the nearby borehole TL48SW2 (some 1500m north-east) contained sand to a depth of 2.9m and that shallow groundwater may be encountered during wet winter months, this is considered to be a high risk.
<b>Other Potential Hazards</b>		
<b>Mining</b>	No	The site is not in an area at risk of mining. However, the site and the land to the east, have both been subject to open cast quarrying of sand and gravel.
<b>Flooding</b>	Yes	The site is classed as Flood Zone 3 and is at high risk of flooding, however the site benefits from flood defences and therefore with suitable mitigation would be suitable for cemetery grounds, however a Flood Risk Assessment may be required to confirm this.
<b>Natural Land Gas</b>	No	Unlikely to encounter gas from natural sources. Land gas could however be encountered from the variable made ground soils which have been deposited in the southern section of the site.
<b>Radon</b>	No	Level of protective measures: NO

### 3.5 Hydrogeology

In lowland areas of the UK with little topographic variation, groundwater is likely to be found at shallow depths of only a few metres. Water table fluctuations will be small as they will be constrained by the ground surface and the base level of the local perennial streams and rivers. In upland areas, precipitation is usually high and the dominantly metamorphic and igneous rocks often have relatively shallow groundwater levels.

This is due to preferential groundwater storage in near-surface weathered and fractured zones with limited drainage into the underlying un-weathered lower permeability rock. Exceptions can occur where higher permeability rocks, such as sandstone or limestone, allow faster throughflow of groundwater towards the nearest stream or other discharge point.

Perched water tables occur where a less permeable horizon (e.g. a clay layer) in an otherwise permeable sequence retains a body of groundwater above the level of the regional water table. They usually occur at shallow depths in alluvial and glacial sediments and can be difficult to identify or to delimit.

An aquifer becomes confined when it is overlain by a less permeable horizon that restricts the upward movement of groundwater. When this less permeable horizon is penetrated (e.g. by drilling), the groundwater level rises above where struck to a level controlled by the hydrostatic pressure. If this is above ground level, overflowing artesian conditions will be encountered. Confined conditions should be anticipated, where possible, in order to plan for the problems they can generate.

Individual sites will always require more detailed assessments to determine the specific impact on groundwater resources. The maps represent conditions only at the ground surface. Where the soil and/or underlying formations have been disturbed or removed the vulnerability class may have been changed and site-specific data will be required. Sites in urban areas and restored or current mineral workings are classified as having high (urban) soil leaching potential until proved otherwise.

**Table 3. Hydrogeology summary**

Geological unit	Groundwater potential	Water level and strikes	Groundwater vulnerability classification
Made Ground	Variable permeability associated with the variable nature of the made ground soils.	Boreholes mapped in close proximity to the site, at the same elevation as the site, encountered groundwater at depths of between 3m - 5m bgl.	Unclassified.
River Terrace Gravels	High permeability and high risk of encountering a mobile groundwater table.	Boreholes mapped in close proximity to the site, at the same elevation as the site, encountered groundwater at depths of between 3m - 5m bgl.	Secondary A Superficial Aquifer – a highly vulnerable Secondary Aquifer.

Geological unit	Groundwater potential	Water level and strikes	Groundwater vulnerability classification
Ampthill Clay	Due to the negligible permeability of the soil, groundwater is unlikely to be encountered, though some perched water in localised coarser deposits could be encountered in places.	Groundwater is unlikely to be encountered in the Ampthill Clay Formation.	Unproductive Aquifer

### 3.6 Groundwater Vulnerability

This section reviews all components of hydrology, geology and topsoil surface water drainage to assess risk notably to groundwater.

#### 3.6.1 Source Protection Zones

The position of the site relevant to current groundwater protection zones is shown in Figure 7.

The proposed development site lies outside of any Source Protection Zone. The nearest SPZ is approximately 16km to the south of the site.

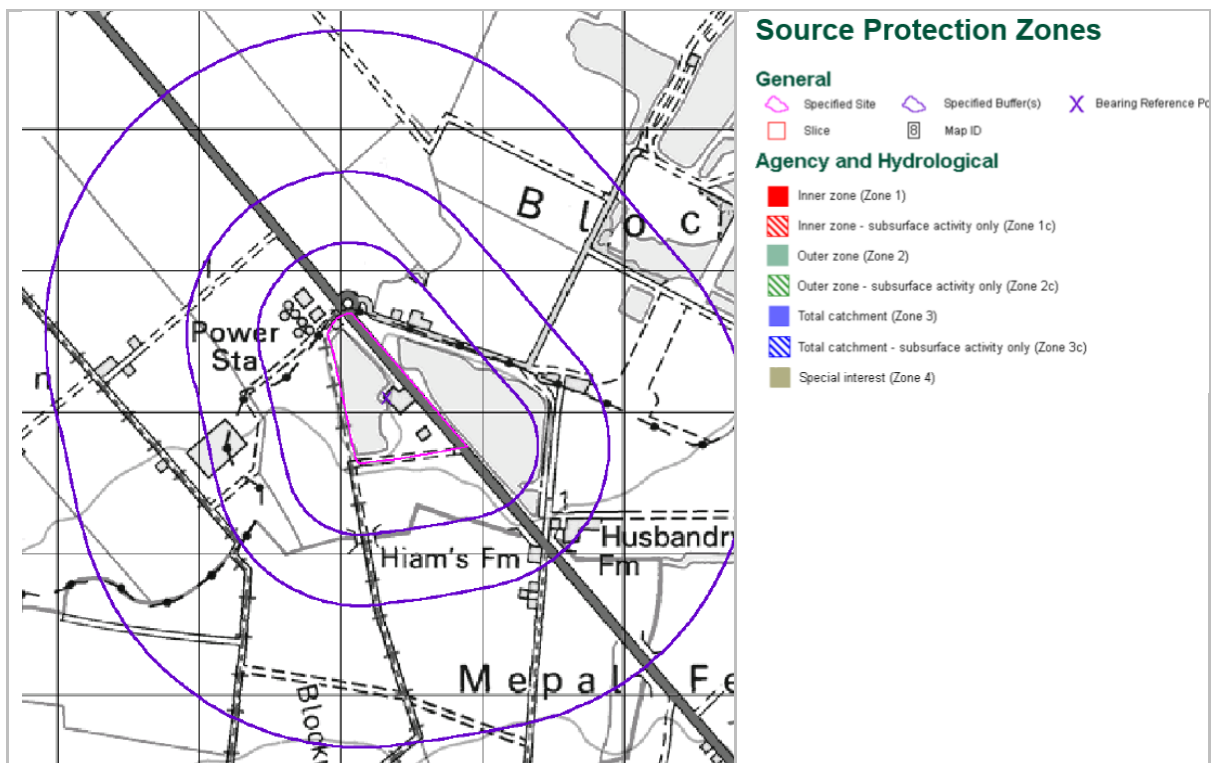

Figure 7. Groundwater Source Protection Zones associated with the site.

Source Protection Zones (SPZs) provide an indication of the risk to groundwater supplies that may result from potentially polluting activities and accidental releases of pollutants. Generally, the closer the activity or release is to a groundwater source the greater the risk. Three zones (an inner, outer and total catchment) are usually defined although a fourth zone (zone of special interest) is occasionally defined.

The Agency has subdivided groundwater source catchments into four zones. Two of these are determined by the travel time of potential pollutants, the third by the source catchment area itself and the fourth is a "Zone of Special Interest". This fourth zone highlights areas where known local conditions mean that potentially polluting activities could impact on a groundwater source even though the area is outside the normal catchment of that source.

- *Zone I (Inner Protection Zone)* - This zone is defined by a travel time of 50-days or less from any point within the zone at, or below, the water table. Additionally, the zone has, as a minimum, a 50-meter radius. It is based principally on biological decay criteria and is designed to protect against the transmission of toxic chemicals and water-borne disease.
- *Zone II (Outer Protection Zone)* - This zone is defined by the 400-day travel time, or 25% of the source catchment area, whichever is larger. The travel time is derived from consideration of the minimum time required to provide delay, dilution and attenuation of slowly degrading pollutants.
- *Zone III (Total catchment)* - This zone is defined as the total area needed to support the abstraction or discharge from the protected groundwater source.
- *Zone of Special Interest* - For some groundwater sources an additional Zone of Special Interest may be defined. These zones highlight areas (mainly on non-aquifers) where known local conditions mean that potentially polluting activities could impact on a groundwater source even though the area is outside the normal catchment of that source.

### **3.6.2 Aquifer Vulnerability**

The Groundwater Vulnerability maps are produced at a 1:100,000 scale. They show, by means of colour coding, those areas of the country where water-bearing rocks (aquifers) are present. They also show the vulnerability of groundwater to pollution. The aquifers are classified into Principal, Secondary and unproductive aquifers according to their physical properties and their consequent value as a resource.

The classification of the land surface reflects the ability of contaminants to leach through the covering soils and pose a potential risk to groundwater at depth. The maps also indicate areas where the presence of low permeability drift may provide additional groundwater protection.

These maps can therefore be used for an initial screening assessment of the vulnerability of groundwater to contaminants applied to the surface of the ground. They do not provide all information relevant to the determination of vulnerability, such as the depth to water table or nature of the drift deposits. Site-specific information would always be needed for a detailed assessment of vulnerability at a given location. The original groundwater vulnerability maps were produced some time ago.

Groundwater Vulnerability Maps provide information on how significant the ground waters are likely to be and if they are vulnerable to pollution occurring at the land surface. The maps have descriptions on them to explain the different aquifer and soil types.

Areas shown as principal aquifers have strategic significance for water resource; they often support large abstractions for the public water supply.

Secondary aquifers have a more localised significance to domestic, agricultural and industrial users (although they may still be used for drinking water). Unproductive aquifers do not store significant amounts of groundwater. However, in some areas they can support local supplies: e.g. small springs feeding individual properties.

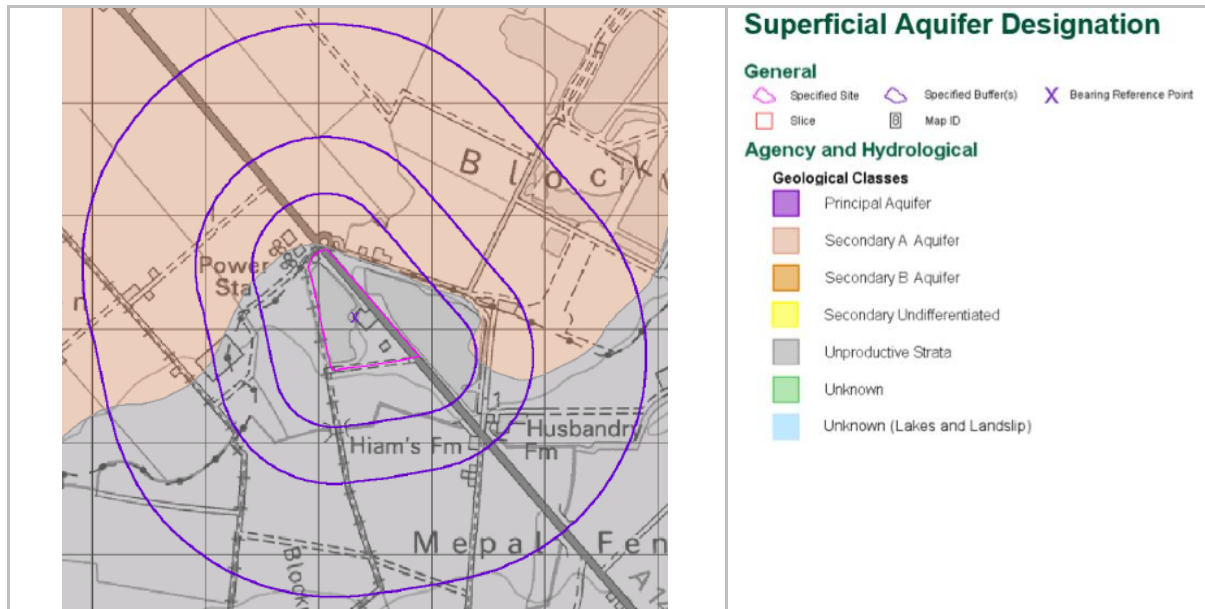

Figure 8. Superficial drift aquifer designation associated with the site.

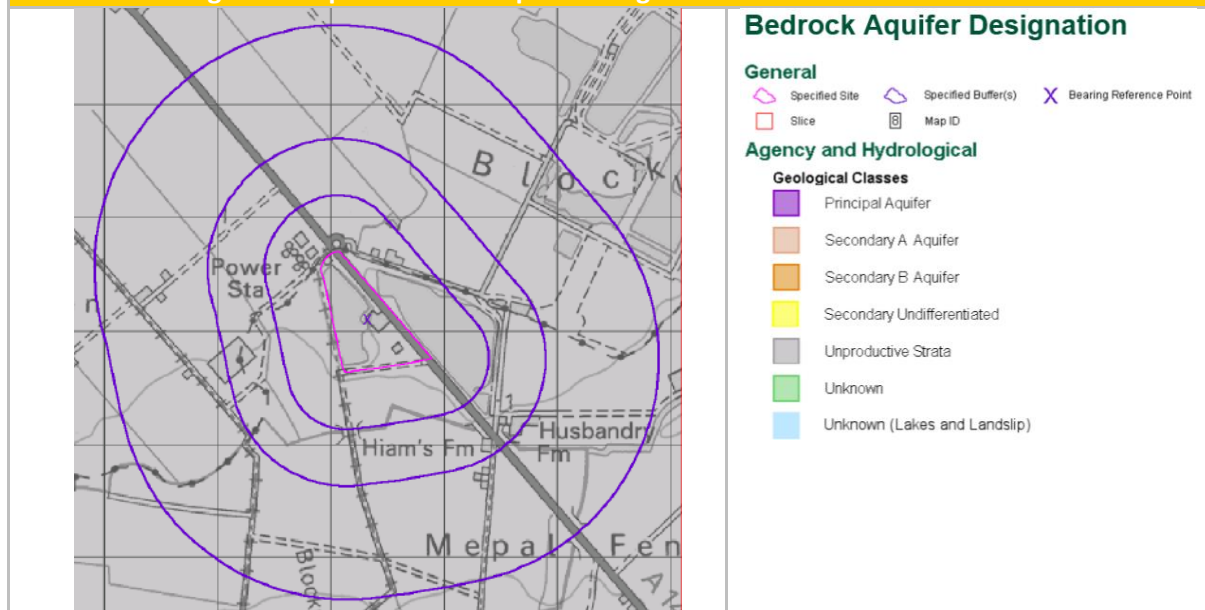

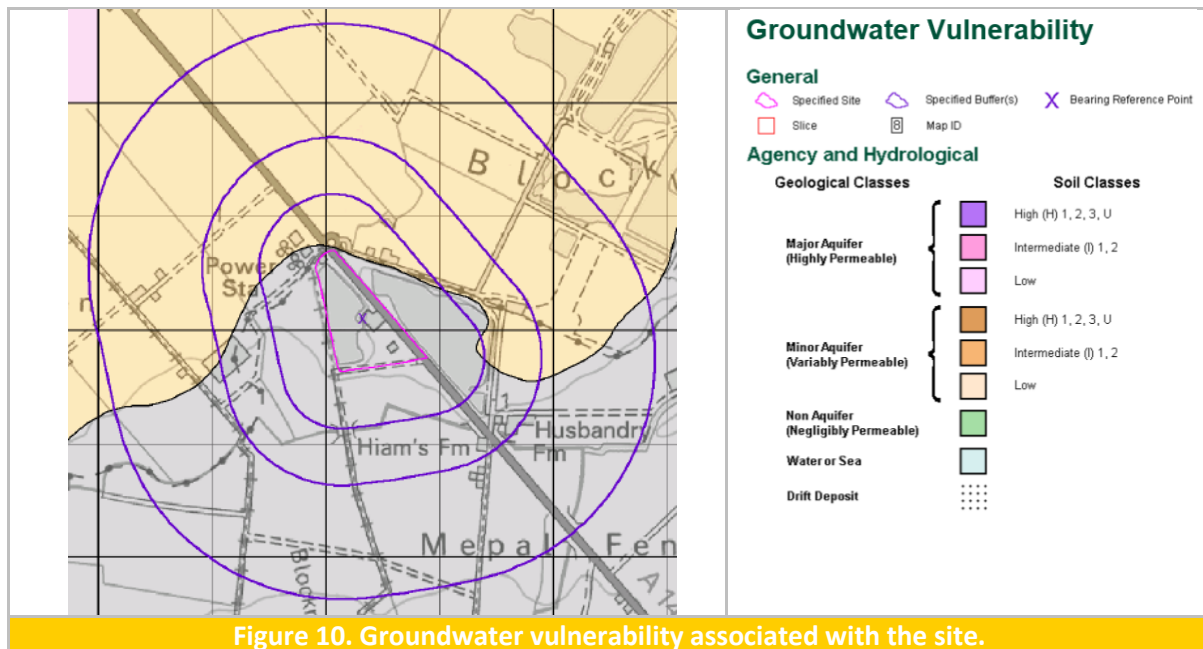

Figure 9. Bedrock aquifer designation associated with the site.

Principal and secondary aquifers may be important in contributing to the base-flow of streams and rivers. The maps show where groundwater is protected from above by rocks with a low permeability, such as glacial clay. They also show the characteristics of the soil above.

Superficial drift deposits which overlay the solid geological strata can sometimes be substantial in thickness. They are often variable in composition changing from highly permeable outwash gravels to low permeability clays over short distances both laterally and vertically. The presence of permeable drift deposits is recognised in the form of secondary aquifers except where these overlie a principal aquifer and they then assume the status of a principal aquifer.

There are no aquifers associated with the mapped superficial deposits and there are also no aquifers associated with the underlying bedrock geology. The site is not within a drinking water safeguard zone however it is within a surface water Nitrate Vulnerable Zone. Though not mapped as an aquifer, the superficial River Terrace Deposits support a secondary aquifer which is locally widespread and is an important source of irrigation water.

### 3.6.3 Flood Risk

The site is within Flood Zone 3 land which is at very high risk of flooding (Figure 11). However, the site does benefit from flood defences.

If areas of impermeable surfaces such as buildings, roads etc. are constructed on a greenfield site, a surface water management system designed in accordance with the principles of Sustainable Urban Drainage Schemes (SUDS) will be required.

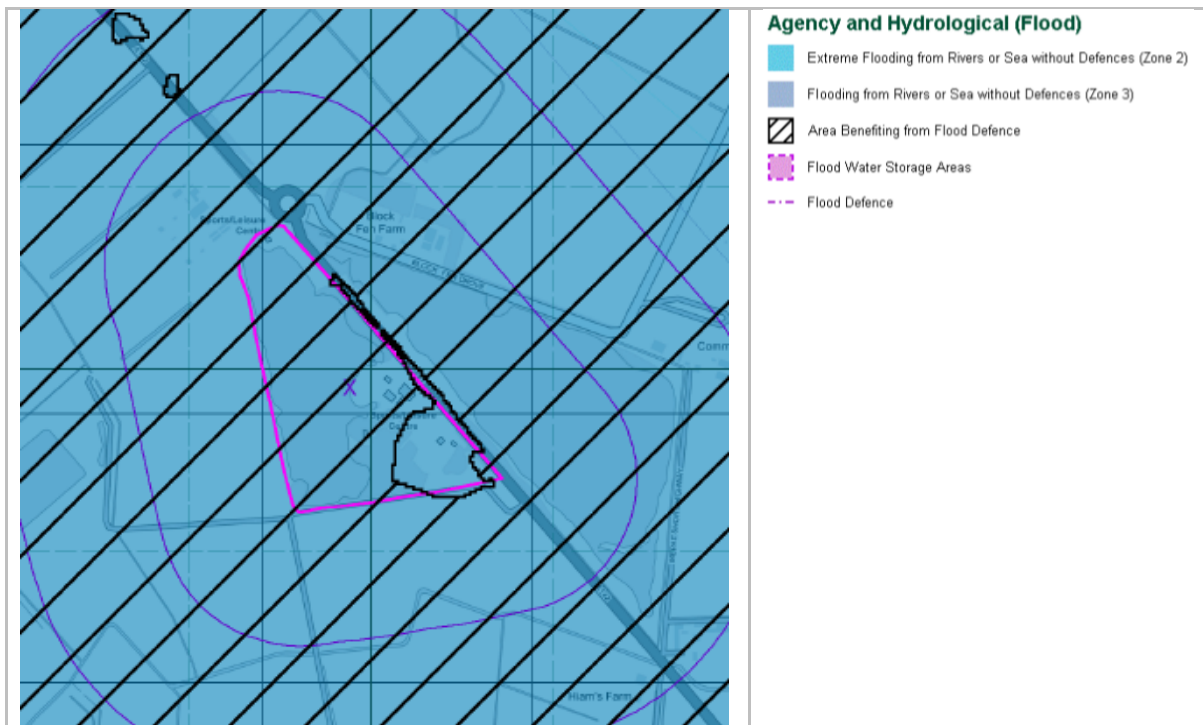

Figure 11. Map of Flood Risk Zones

### 3.6.4 Wells in the vicinity of the site

There are 26 groundwater abstraction licenses mapped within 250m of the subject site. The abstractions listed all relate to spray irrigation for general agriculture or commercial activities and are abstracting from surface water features and groundwater abstraction points. There are however no potable abstraction wells listed within 1km of the site.

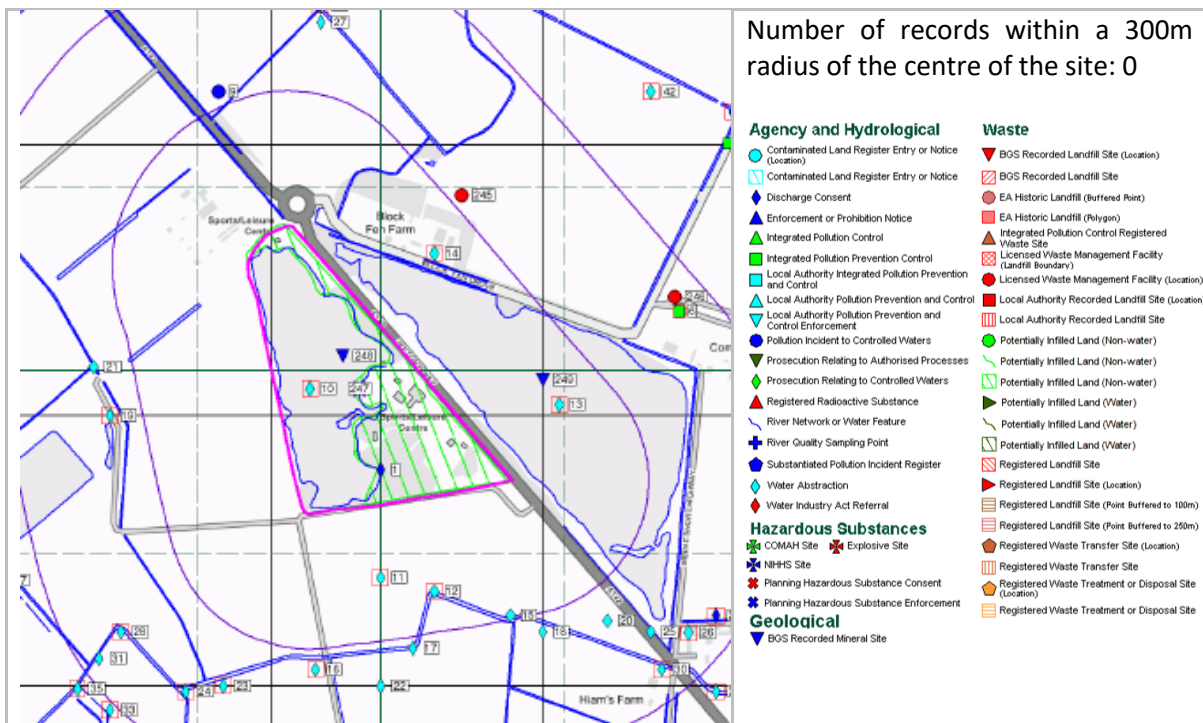

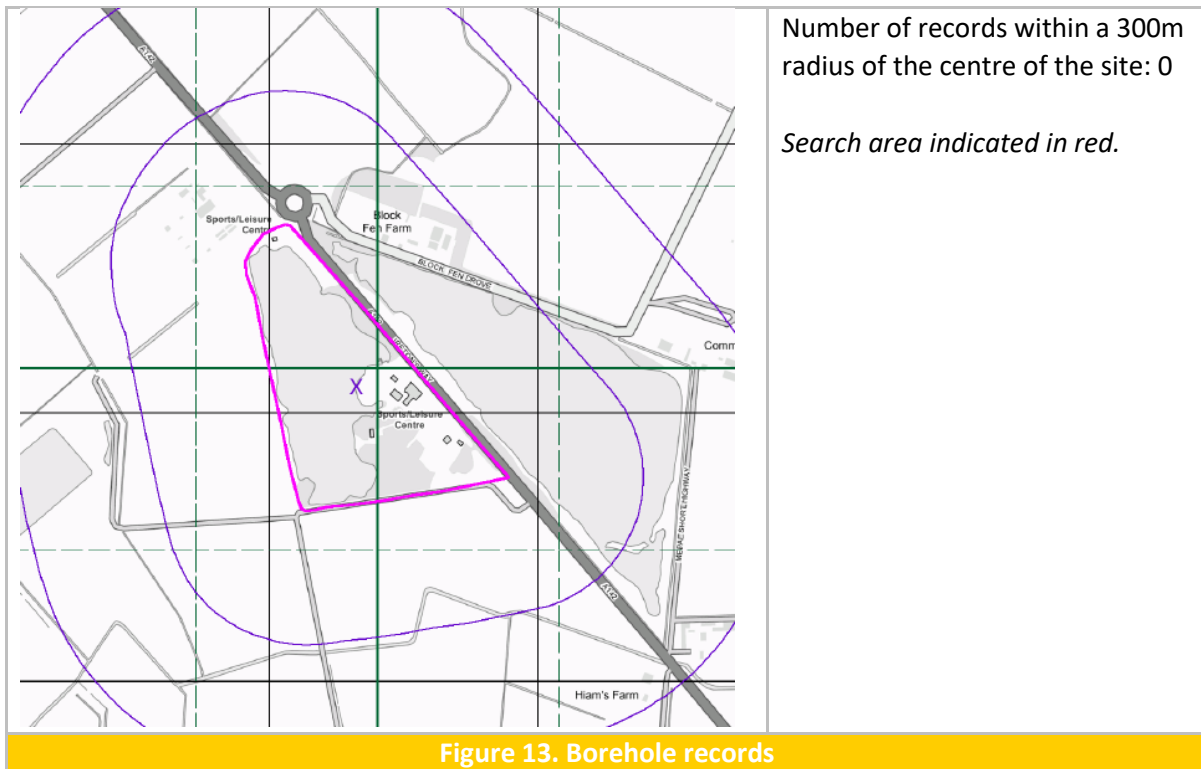

Figure 12. Well records

### 3.6.5 Borehole records in the vicinity of the site

### 3.7 Meteorological Data

The agroclimatic index number for this site is 28 with a mean annual rainfall of 574 mm, the Standard Average Annual Rainfall (SAAR) for the site itself is 539 mm.

### 3.8 Surface Water Issues

There are several areas, as shown in Figure 14 below, which are liable to surface water flooding on the raised area of land in the southeastern corner of the site. Any works which might increase the risk of flooding on or off site need to be identified and the risks assessed and mitigated using a suitable SUDS compliant approach.

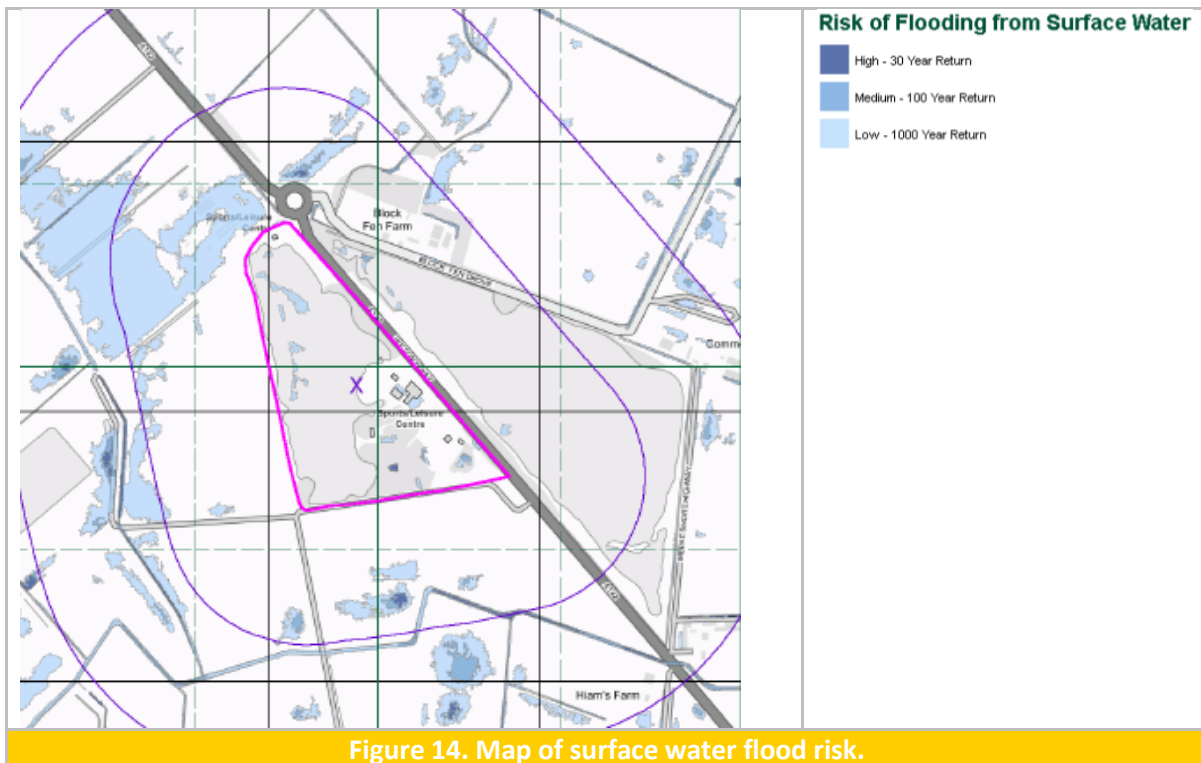

Figure 14. Map of surface water flood risk.

## 4 Intrusive Investigation

### 4.1 General Site Description

The site comprises a disused former Outdoor Centre, which contained numerous derelict buildings and large areas of car park on the central and eastern side of the site. To the south of the car park is an additional derelict building, associated with the former caravan/camping club, which has been heavily vandalised and damaged. The land to the south and east of these buildings comprises overgrown open land with mixed self-sown shrubs and semi mature trees along with small areas of woodland and small ponds. Evidence of sand across the surface of the site and significant burrowing was apparent all across the surface of the site in the southern section.

In the centre of the site, to the southeast of the main building, a large raised soil mound, approximately 2 - 4m in height is situated. This mound appears to have been formed with reject sand, however, there is a risk that other types of anthropogenic made ground could be encountered. Adjacent to the soil mound were further old derelict buildings and what appears to be an old landing stage onto the lake.

The lake covers the majority of the site, and was observed to be relatively still and clean, with clear water observed on the edges of the lake where access was available. The base of the lake appeared to be made up of sand and gravel, as would be expected given the geology.

## 4.2 Site Topography

The digital terrain map below shows the site location and mapped elevation changes across the subject site.

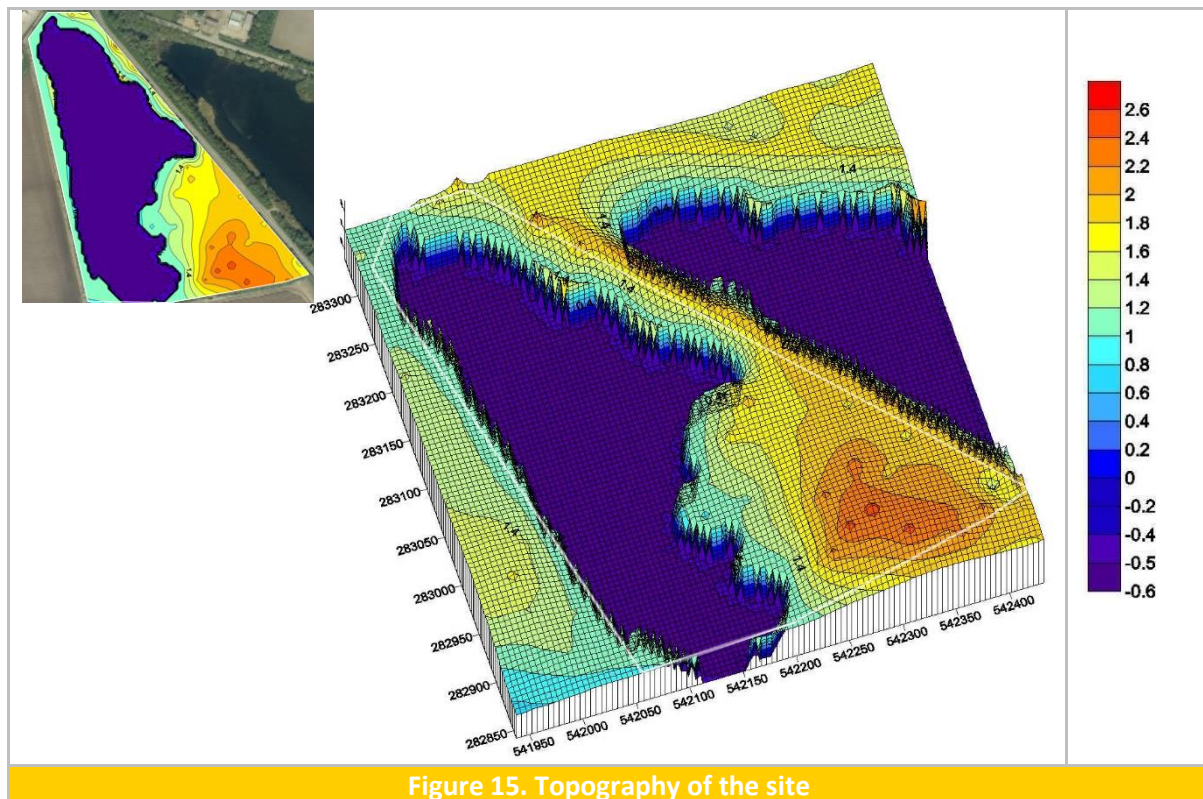

Figure 15. Topography of the site

## 4.3 Site Investigation

An intrusive site investigation was undertaken on the 14<sup>th</sup> of November 2019, with a total of 7 trial pits excavated across the proposed burial area to provide an assessment of the ground conditions, to identify the presence and composition of made ground soils and to assess whether any shallow groundwater is encountered on site.

The trial pits were excavated at the approximate locations shown below in Figure 16, to maximum depths of 3.3m. It was difficult to achieve target depths in the pits due to the instability of the loose sandy soils encountered.

Figure 16. Exploratory Hole Location Plan

#### 4.4 Soils as Found

The soils encountered across the site were found to be highly variable and in general comprised made ground soils to depth. At the location of TP107, natural soils, comprising laminated sands were encountered to the base of the pit.

A general summary of the soils as found on site is provided in Table 4.

**Table 4. Soils as Found**  
TP102, 103, 104 and 105

Depth m bgl (Top to Base)	Soil Type	Description
GL to 1.4m/1.7m	Made Ground	MADE GROUND comprising highly variable reworked orange-brown clay with abundant fine to coarse flint, brick rubble and whole bricks, concrete, black top, plastic, wood and occasional slate fragments.  At the location of TP105 large cobble sized concrete rubble was encountered and occasional fragments of <u>possible bitumen bound asbestos</u> .
1.4m/1.7m to 2.9m/3.3m	Made Ground	MADE GROUND comprising very loose, poorly compacted, yellowish orange fine to medium SAND. Numerous side wall collapses and trench instability observed.

**TP101 and TP106**

Depth m bgl (Top to Base)	Soil Type	Description
GL to 0.15m/0.3m	Topsoil	Dark brown silty fine sandy TOPSOIL.
0.15m/0.3m to 2.0m to 3.0m	Made Ground	MADE GROUND comprising very loose, poorly compacted, yellowish orange fine to medium SAND. Numerous side wall collapses and trench instability observed.
2.0m to 2.4m	Sand	Wet, saturated pale grey, silty organic fine SAND with occasional shell fragments.

At the location of TP107, natural soils comprising thinly laminated orangish yellow silty fine SAND were encountered. These soils were still observed to be loose, with multiple side wall collapses observed.

#### 4.5 Groundwater

Groundwater was only encountered at TP106, which is in close proximity to the lake. In this pit, saturated natural soils were observed below 2.0m bgl. The nature of the water strike was difficult to assess due to trench stability issues leading to repeated side wall collapses and continual backfilling of the trial pit.

To investigate seasonal variations and determine the depth to groundwater within the burial area, it is recommended that groundwater monitoring wells be installed across the proposed burial area (see section 6 below).

#### 4.6 Trench Stability

During the excavation of the trial pits, evidence of significant trench instability was observed within the loose and poorly compacted made ground soils. Trench instability was also observed in the natural soils at the location of TP107.

Based on the above, even single depth burial excavations for natural burials would be considered difficult, due to the likelihood of large scale side wall collapse. Any excavation will require close lateral support, which should provide sufficient temporary support to maintain the stability of the excavation.

**No personnel should enter any excavation before close lateral support is installed due to the risk of collapse.** Consideration should also be given to moving grave arisings further back from open excavations to help reduce lateral loads on the side walls of open excavations.

## 5 Pollutant Risk

The amount of annual burials will have a significant influence on the cumulative ammoniacal nitrogen concentration. The estimated burial numbers are assumed to be less than 30 per annum, and as such the risk would be considered moderate to high.

## Pathogens

There has been some evidence from recent studies of the occurrence of Enterococci and Clostridium bacteria found in drainage water of cemeteries. Enterococci are bacteria that are commonly found in the bowel of normal healthy individuals. They can cause a range of illnesses including urinary tract infections, bacteraemia (blood stream infections) and wound infections.

The two most common species of Enterococci are *E. faecalis* and *E. faecium*. During the mid-1980s, enterococci with resistance to glycopeptide antibiotics such as vancomycin and teicoplanin emerged, termed glycopeptide-resistant enterococci (GRE). Most GRE are *E. faecium*.

Due to the nature of the soil and geomorphology, there is likely to be significant movement of pathogenic organisms, notably *Pseudomonas aeruginosa* and Faecal streptococci. Pathogens tend to be short lived away from the host and if there is no immediate groundwater risk or potable well supply, the risk may be considered acceptably low. This site is underlain by highly permeable made ground soils comprising loosely placed reject sand and at shallow depth variable clayey made ground with brick, concrete, timber, metal and other building rubble. Such material would offer little in the way of protection to the underlying groundwater table or the water quality in the adjacent lake, and there is a high risk that pathogens and other burial contaminants would enter these receptors unmitigated.

## 6 Groundwater Monitoring

A total of six hollow stem boreholes were drilled across the site to enable the installation of groundwater monitoring wells to assess the impact of groundwater levels on the future burial area. The boreholes were drilled at the approximate locations shown below in Figure 17, to maximum depths of 6.00m bgl. The boreholes were distributed across the entire site to assess soil variability, depth to groundwater and to enable future monitoring works.

Figure 17. Exploratory Hole Location Plan

The table below summarises the maximum and minimum depth to groundwater at each borehole location in terms of m bgl and m AOD, and the observed variance in groundwater levels.

**Table 5. Groundwater Monitoring Data**

Location	Water Level m bgl		Water Level m AOD	
	Minimum	Maximum	Minimum	Maximum
BH1	2.93m bgl	3.5m bgl	-0.95	-1.52
BH2	2.81m bgl	3.3m bgl	-0.99	-1.48
BH3	3.27m bgl	3.8m bgl	-1.05	-1.58
BH4	3.57m bgl	4.0m bgl	-0.94	-1.37
BH5	3.45m bgl	3.9m bgl	-0.85	-1.3
BH6	3.3m bgl	3.8m bgl	-0.67	-1.17

The results of the groundwater monitoring from across the site indicates that any proposed burials, be considered suitable in terms of depth to groundwater. As a 1.4m burial depth would provide at worst case, an unsaturated zone of at least 1.9m considering the lowest minimum value for boreholes 4, 5 and 6, which were drilled on site within the proposed burial area. Given the permeability of the sandy soils in this area, this unsaturated zone would provide a degree of protection to the underlying water table.

## 7 Depth of Burial

Based on the nature of the soils encountered and the observed trench instability, it is recommended that burials be restricted to single depth burials only due to the significant risks associated with large scale side wall collapse.

Single depth burials would likely be placed at a shallow enough depth to provide the required 1m unsaturated zone beneath the base of the burial as proven by the groundwater monitoring undertaken to date.

## 8 Greywater Management

Groundwater protection is a statutory requirement for all cemetery sites under the Water Resources Act. The Environment Agency have also laid down strict guidelines for the development of new cemeteries and operation of all existing cemeteries with active burial and reopens, which include but are not limited to the following:

- Graves should not hold any standing water when dug.
- There should be at least 1 metre between base of grave and water table; more if the soil has high infiltration rates.
- Graves should be at least 250m away from wells and potable water supplies.
- Pumping out of graves and discharging “grey” water directly or indirectly into surface or groundwater sources if found to be polluted is an offence under the Groundwater Regulations 1998.
- No burials within 10 meters of land drains.

During the winter months, it is a common requirement to pump water out of newly opened graves. There are a number of reasons why water enters graves, it is important therefore, to determine where the water is coming from. There are usually three main sources:

### **8.1 Surface Water**

In the winter and during periods of heavy and sustained rainfall, surface water is likely to be the most common source of water seepage into graves particularly on site situated on relatively impermeable subsoils such as clay. The shallow soil profile soon becomes saturated and the soil exceeds field capacity, meaning that all the soil's pore space is filled with water. The greater the water input, the deeper this waterlogged layer becomes. Clay soils may only allow infiltration rates of between 2mm to 3 mm per hour, however, if the soil is consolidated, then this rate could be reduced to less than 1 mm per day leading to prolonged periods of standing water and rapid runoff from sites when rainfall begins.

In high rainfall events (10-15 mm per hour), the upper horizon (topsoil) soon becomes saturated as water movement downwards is impeded by the less impermeable soils below, eventually precipitation exceeds the speed of downward infiltration and excess surface water then moves horizontally and generally down slope over the surface, ponding in depressions such as over new graves or in areas where older graves have not been suitably topped-up. Furthermore, if the drainage network designed to capture surface water and drain it away from burial areas is not adequately maintained then these systems can backup leading to surface water flooding.

Excavating a new grave in a previously unoccupied plot of land will allow water to flow through the soil into the newly excavated grave. This water in most cases will be unpolluted, provided it is a new grave up-slope from existing graves. Pumping is an option and is likely to pose little pollution risk if discharged to land and allowed to soak away, alternatively water can be discharged into the surface water or foul-water drainage system although permission from the water company will be required.

If a grave is being re-opened, even if the soil has been compacted over the previous burial, it is likely some water will have gathered around the previous interment. In the worst cases this may extend up through the soil to the depth of the next burial. This water will be polluted and should be treated as grey water. It must not be discharged untreated into a surface water or groundwater outfall, nor should it be pumped onto the surface. If the burial is relatively recent, pathogen loading in the water could be high and may present an immediate biological risk to staff and visitors if discharged onto the surface. Even for an old burial the water is likely to be chemically contaminated, posing a risk to the receiving waters. In all cases such water should be disposed of either to a foul sewer (with appropriate permission) or be tankered away to a suitable water treatment works.

The better the compaction of the backfill over a grave, the less likely water is to move through the soil and gather around a coffin at burial depth. Equally, if the grave can be regularly topped up to avoid the formation of a depression over the grave then water will run off the surface and away from the grave rather than ponding over a grave in infiltrating down to burial depth.

If the water in the burial has a sheen/odour and is anticipated to be 'greywater' then this water cannot be discharged onto land or into drains as this would breach guidelines with respect to discharge of suspected polluted water.

## 8.2 Groundwater

If, when digging a grave, water appears to enter the pit at lower levels and / or through the base of the pit it is almost certainly groundwater. The speed at which the water enters a pit or grave can vary depending the nature of the soils. If groundwater is encountered in a freely draining soil such as a fractured weathered bedrock or a highly permeable sand/gravel then the flow may well be rapid, filling the pit or grave quickly. However, if groundwater is encountered in an intergranular soil such as fine sands/silt, then the rate of inflow may be slow and, in some cases, may not be instantly apparent. If left for an hour or so and re-examined, groundwater may appear as slow seepage into the pit or as a sheen of water droplets on the pit base and sides. However, both cases could indicate the presence of groundwater within burial depth and accordingly it is not appropriate to undertake a burial in such conditions as it would be considered in breach of two statutory requirements.

- Graves should not hold any standing water when dug.
- There should be at least 1 metre between base of grave and water table; more if the soil has high infiltration rates.

It should be noted, however, that on some sites a shallow perched water table may be encountered which has no direct connection to groundwater or surface water features. Often sites with a clay soil may contain pockets made up of sand and gravel known as "lenses". If a grave is dug into such a lens, it will cause the water to drain from the lens into the grave. The size of the lens will determine the speed and quantity of water ingress into the grave. Depending on whether the new burial is in close proximity to other burials and depending if other graves in the cemetery are at, or above, the level of these lenses, the water entering the burial may or may not be considered to be contaminated. When considering pumping out, this water should be managed as part of a health and safety management approach (see later discussion).

## 8.3 Intergrave Seepage

As discussed previously, surface water arising from periods of heavy or sustained rainfall on heavy clay soils will migrate to depressions, which in cemeteries are often associated with settlement of graves. The backfill material of a grave is usually less consolidated than the surrounding undisturbed soil due to the fact that the soils has been reworked and placed back leaving fissures and voids in the soils. If the surrounding matrix is less permeable, water will accumulate in the pore spaces and voids within the grave. This "free water" is mobile and is under a "head" of pressure which increases with depth.

If a new grave is dug downslope of, or adjacent to, an existing grave it is likely that seepage of "grey" water from the adjacent plot will occur. Based on the age of the adjacent burial (<10 years or younger), there is a significant risk that the water draining into the excavation will be contaminated. Recent evidence shows that this greywater may contain clostridium and streptococcal bacteria. Concern has now also been raised about the possible presence of the CJD vector.

Pumping "grey" water without adequate protection of water courses, staff and public is potentially dangerous and irresponsible. Environment Agency representative advice as of January 2007 is as follows:

*"Grey water should be managed in the first instance by the prevention of surface water entering grave plots, old and new. This can be done by installing cut-off or surface management drainage systems. If water is subsequently pumped from the grave, the water must be stored and subsequently disposed of by a professional environmental waste management company. Alternatively, the water can be treated on site by either mobile or permanent treatment systems prior to discharge or recycling."*

## 9 Archaeology

It is recommended that consultation with the county archaeological team be undertaken to ascertain any archaeological interest in the area. Given that the site was quarried and reject sand material and made ground soils used to infill the quarry the likelihood of encountering archaeology is however considered to be very low.

## 10 Risk Evaluation

### Assessment of general hazards.

The potential of a number of pollutant pathways and the degree of associated risk assessed numerically on a 0-10 score with 10 being the highest risk is shown in Table 6. From the resultant data, the final values are assessed against burial number and a determinant of risk calculated from EA flow charts and nomographs.

**Table 6. Summary of pollution risk associated with the site**

Risk	Assessment (High, Moderate, Low)	Comment	Score
Burials per annum	High	Burial numbers are anticipated to be less than 30 per annum. Given the highly permeable nature of the underlying soils the risk associated with even low numbers of burials is considered to be high due to the proximity of sensitive waterbodies on site.	-
Drift / superficial data	High	The BGS classify the superficial deposits as Peat, however, the site has historically been quarried and subsequently infilled with reject Sand.  The made ground soil encountered on site provides little in the way of mitigation against the movement of burial contaminants and as such is considered to be a high risk.	7-8
Drift thickness	Very Low	Nearby borehole records show that the underlying Ampthill Clay is encountered at depths between 3.2m - 5.3m bgl. The trial pits and boreholes excavated to maximum depths of 6.0m bgl and did not encounter bedrock.  It is therefore estimated that the depth to bedrock is greater than 5m. Accordingly, the risk is classed as very low.	1-2

Risk	Assessment (High, Moderate, Low)	Comment	Score
Depth to Water Table	Very High	Groundwater was not encountered in the majority of the trial pits excavated to depths of 3.3m bgl. Water was encountered in one trial pit, excavated at a lower elevation, at a depth of approximately 2.0m bgl.  Groundwater monitoring from the boreholes on site has recorded water levels at depth of between 3-4m bgl.	9-10
Flow mechanism	High	Considered high due to the permeable nature of the sand deposits encountered across the site.	7-8
Proximity to Wells or potable water source	Low	There are numerous wells in close proximity to the site, all of which are associated with spray irrigation for general agricultural use. There are no mapped potable wells within 1km of the site.	3-4
Aquifer Type	Moderate	The site is not mapped on either a superficial or bedrock aquifer. However, the River Terrace Gravels mapped directly off site, and encountered on site are mapped as a Secondary A Aquifer of high vulnerability.	5-6
Abstractions and SPZ	Very Low	The site is not situated within a Source Protection Zone. The nearest groundwater source protection zone is approximately 16km to the south of the site.	1-2
Proximity to water course/springs	High	The nearest watercourse comprises a large lake situated directly west of the proposed burial area.  This is at high risk from burial contaminants.	9-10
Proximity to land drains	Very Low	Given that the site was a former quarry, and that the land has been raised with reject sand, it is very unlikely that land drains are situated on the site.	1-2
Met data	Moderate to High	Annual rainfall is low.	N/A
Proximity to housing	Low	Residential housing not in close proximity of the site	N/A
SSSI	Low		N/A
Archaeology	Low	None observed but will require County Archaeologist assessment	N/A
		<b>Total (Minimum to Maximum)</b>	<b>43-52</b>

Table 6 is assessed using the groundwater vulnerability-ranking criteria in Table 7. The total score comes to 43-52 and is considered as a moderate to high risk, dependent on burial rates. These data are then assessed against a range of burial rates per annum on the groundwater risk nomograph p.37 of PP223.

The final assessment of risk for this site according to the nomograph (Figure 18), would class it as being moderate risk where burials are less than 20 per year, or high risk where burials exceed 20 per year.

**Table 7. Groundwater risk ranking**

Ranking	Very Low 1-2	Low 3-4	Moderate 5-6	High 7-8	Very High 9-10
<b>Drift Type</b>	Clay	Silt	Silty sand	Sand/gravel	Absent
<b>Drift Thickness</b>	>5 m	>3-5 m	3 m	0-3 m	Absent
<b>Depth to water Table</b>	>25 m	11 – 25 m	10 m	5 – 9 m	<5m
<b>Flow mechanism</b>	Intergranular				Fissured
<b>Proximity to wells</b>					Within 250 m
<b>Aquifer type</b>	Non Aquifer		Secondary aquifer		Principal aquifer
<b>Abstractions and SPZs</b>	Outside Zone III	Within Zone III	Close to boundary of Zone II	Within Zone II	Within Zone I
<b>Water courses and springs</b>	>100m	>70m<100m	>50 <70 m	>30 <50 m	<30 m
<b>Drains</b>	>100 m	>40 <100 m	30 – 40 m	>10 <30 m	<10 m

10.1 Groundwater Risk Nomograph

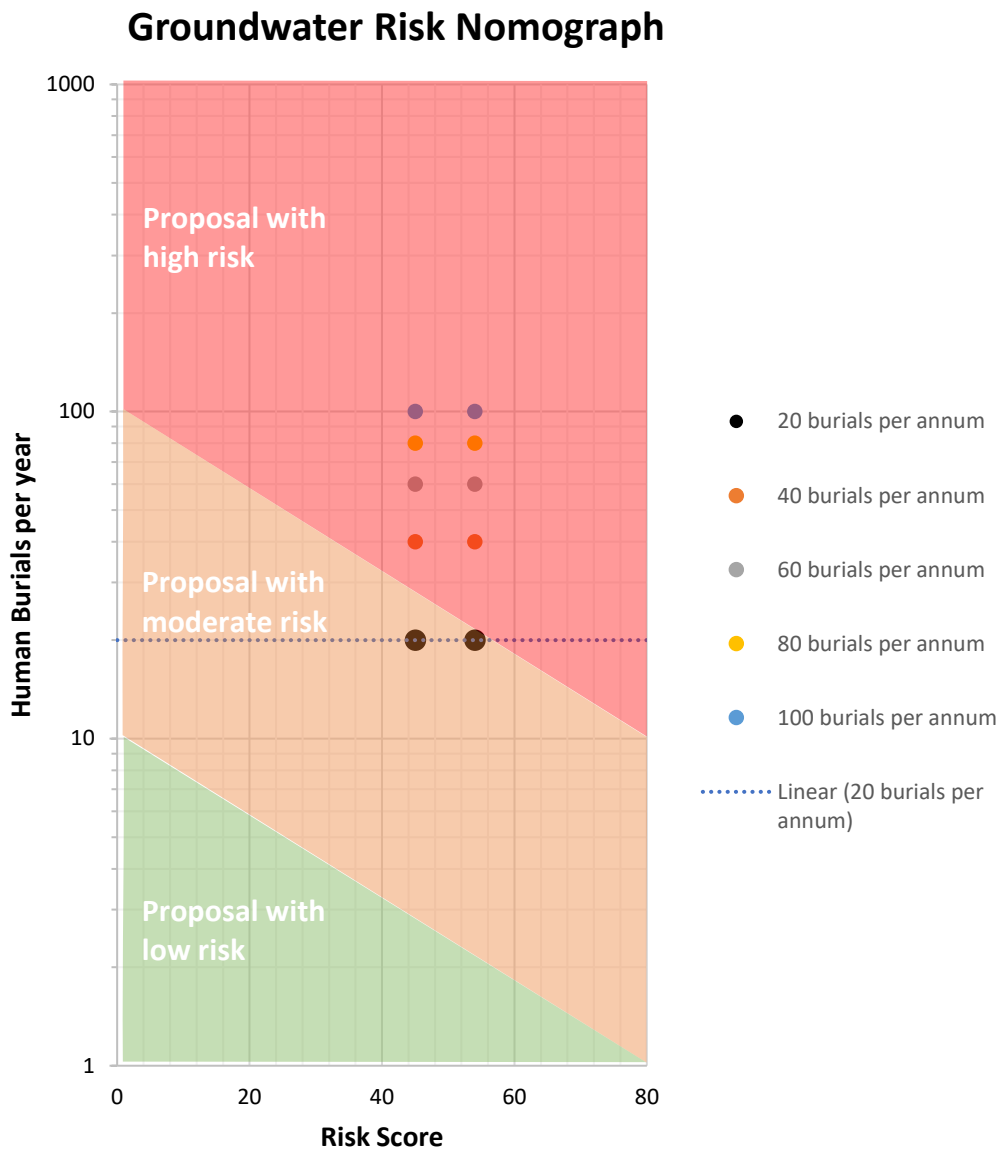

Figure 18. Groundwater Risk Nomograph

---

## 11 Conclusion

Based on this assessment, the site is considered to be moderate to high risk, with a risk score 43-52 calculated for the site. The highest risk scores (9-10) were attributed to the presence of groundwater table less than 5m bgl and the close proximity of the lake to the west of the proposed burial ground. The final assessment of risk for this site would class it as being a moderate risk for less than 20 burials per annum, a moderate to high risk for 20-25 burials per annum and a high risk for over 25 burials per annum.

The proposed burial area is situated in made ground soils which were used to backfill the former sand pit. These soils were found to comprise loose, poorly compacted sand, which in some areas was overlain by variable clayey anthropogenic made ground soils which contained brick, concrete, timber, metal and other detrital material. At the location of TP105, large concrete rubble and other demolition material, including possible asbestos containing materials was observed, indicating that the nature of the imported material may vary significantly across the site. These soils are considered to offer little in the way of mitigation against burial contaminants migrating away from the source and into the nearest receptor, the lake to the west of the site.

In addition, due to the variability of the materials observed there is a risk that contaminated soils may be encountered which would pose a risk to groundworkers and mourners if excavated and left exposed at the surface of the site.

Based on the nature of the soils encountered and the observed trench instability, it is recommended that burials be restricted to single depth burials only due to the significant risks associated with large scale side wall collapse. Single depth burials would likely be placed at a shallow enough depth to provide the required 1m unsaturated zone beneath the base of the burial as proven by the groundwater monitoring work undertaken to date.

The site is not considered to be situated in a sensitive groundwater area, with no groundwater source protection zones mapped on site and no potable abstraction wells mapped within 1km of the site. In terms of receptors, the nearest would be the lake to the west and to the east, which may have ecological value, which could be impacted by changes in water quality associated with burial contaminants such as nitrates and ammonia. The freely draining nature of soils offers little in the way of protection to these sensitive sources.

Given the above, the presence of proposed future burials does provide a source of potential pollutants, such as ammonia, nitrate, formaldehyde and bacteria contaminants, which could have a significant impact on the water quality beneath the site and in the lake to the west and to the east.

Consideration should be given to undertaking pollutants flux modelling to assess the impact burials would have on the water quality of adjacent surface water features and the underlying groundwater.

### Geology 1:50,000 Maps

This report contains geological map extracts taken from the BGS Digital Geological map of Great Britain at 1:50,000 scale and is designed for users carrying out preliminary site assessments who require geological maps for the area around the site. This mapping may be more up to date than previously published paper maps.

The various geological layers - artificial and landslip deposits, superficial geology and solid (bedrock) geology are displayed in separate maps, but superimposed on the final 'Combined Surface Geology' map. All map legends feature on this page. Not all layers have complete nationwide coverage, so availability of data for relevant map sheets is indicated below.

### Geology 1:50,000 Maps Coverage

## Artificial Ground and Landslip

Artificial ground is a term used by BGS for those areas where the ground surface has been significantly modified by human activity. Information about previously developed ground is especially important, as it is often associated with potentially contaminated material, unpredictable engineering conditions and unstable ground.

Artificial ground includes:

- Made ground - man-made deposits such as embankments and spoil heaps on the natural ground surface.
- Worked ground - areas where the ground has been cut away such as quarries and road cuttings.
- Infilled ground - areas where the ground has been cut away then wholly or partially backfilled.
- Landscaped ground - areas where the surface has been reshaped.
- Disturbed ground - areas of ill-defined shallow or near surface mineral workings where it is impracticable to map made and worked ground separately.

Mass movement (landslip) deposits on BGS geological maps are primarily superficial deposits that have moved down slope under gravity to form landslips. These affect bedrock, other superficial deposits and artificial ground. The dataset also includes foundered strata, where the ground has collapsed due to subsidence.

## Superficial Geology

Superficial Deposits are the youngest geological deposits formed during the most recent period of geological time, the Quaternary, which extends back about 1.8 million years from the present.

They rest on older deposits or rocks referred to as Bedrock. This dataset contains Superficial deposits that are of natural origin and 'in place'. Other superficial strata may be held in the Mass Movement dataset where they have been moved, or in the Artificial Ground dataset where they are of man-made origin.

Most of these Superficial deposits are unconsolidated sediments such as gravel, sand, silt and clay, and onshore they form relatively thin, often discontinuous patches or larger spreads.

## Bedrock and Faults

Bedrock geology is a term used for the main mass of rocks forming the Earth and are present everywhere, whether exposed at the surface in outcrops or concealed beneath superficial deposits or water.

The bedrock has formed over vast lengths of geological time ranging from ancient and highly altered rocks of the Proterozoic, some 2500 million years ago, or older, up to the relatively young Pliocene, 1.8 million years ago.

The bedrock geology includes many lithologies, often classified into three types based on origin: igneous, metamorphic and sedimentary.

The BGS Faults and Rock Segments dataset includes geological faults (e.g. normal, thrust), and thin beds mapped as lines (e.g. coal seam, gypsum bed). Some of these are linked to other particular 1:50,000 Geology datasets, for example, coal seams are part of the bedrock sequence, most faults and mineral veins primarily affect the bedrock but cut across the strata and post date its deposition.

## Combined Surface Geology

The Combined Surface Geology map combines all the previous maps into one combined geological overview of your site.

Please consult the legends to the previous maps to interpret the Combined "Surface Geology" map.

## Additional Information

More information on 1:50,000 Geological mapping and explanations of rock classifications can be found on the BGS website. Using the LEX Codes in this report, further descriptions of rock types can be obtained by interrogating the 'BGS Lexicon of Named Rock Units'. This database can be accessed by following the 'Information and Data' link on the BGS website.

### Introduction

The Environment Act 1995 has made site sensitivity a key issue, as the legislation pays as much attention to the pathways by which contamination could spread, and to the vulnerable targets of contamination, as it does the potential sources of contamination. For this reason, Landmark's Site Sensitivity maps and Datasheet(s) place great emphasis on statutory data provided by the Environment Agency/Natural Resources Wales and the Scottish Environment Protection Agency; it also incorporates data from Natural England (and the Scottish and Welsh equivalents) and Local Authorities; and highlights hydrogeological features required by environmental and geotechnical consultants. It does not include any information concerning past uses of land. The datasheet is produced by querying the Landmark database to a distance defined by the client from a site boundary provided by the client. In this datasheet the National Grid References (NGRs) are rounded to the nearest 10m in accordance with Landmark's agreements with a number of Data Suppliers.
