Cornerstone Technical Report

Our ref: DS0721-SE57JZ/JB Author: Andrew Dallen Name Mr. Khawaja Client Mr. Khawaja **Address** 8 Addington Square Contact **Christopher Read** London 4th August 2021 **Initial visit** SE5 7JZ 10th August 2021 Return visit

Scope

Following instruction from Mr. Khawaja, attend the above property to report on moisture conditions and were possible identify sources of loss moisture affecting the structure.

Report

1.0 Property:

The property is a large Grade II listed semi-detached dwelling dating from the early 1800's and, a review of London Street maps suggest it possibly pre-dates 1820. Original areas are of solid wall construction part rendered and decorated to the exterior with a mix of timber suspended floors and ground supported floor slabs noted through the ground floor. There is a range of single storey rooms added to the rear of the property and are of reasonable modern cavity wall construction

1.1 Period of construction – Concrete floor slabs:

In 1965 it became a matter of regulation that ground supported concrete floor slabs should have a DPM (Damp Proof Membrane) in their construction to prevent ground moisture from migrating to the surface of the slab. Prior to this date it was the floor finish which acted as the DPM for example, thermoplastic tiles set on bitumen or wood block flooring set on bitumen etc.

1.2 Period of construction – Wall structures

In and around 1875, a public health act and aligned local by-laws, made it a matter of regulation DPC's (Damp Proof Courses) should be incorporated in wall structures affected by ground moisture to prevent the migration of ground moisture into the upper wall structures through capillary action. Prior to this date walls tended to be constructed with lime-based materials. Lime has a high permeability factor which allow it to vent structural moisture freely which will in turn tend to limit the vertical climb of ground related moisture in affected walls structures.

3.0 Conclusion:

A detailed moisture survey has been carried out through the property to allow an understanding as to the moisture condition of the structure and where possible, identify likely routes of water ingress. In all cases every effort has been taken to ensure reported readings are representative of the surveyed areas.

3.1 Limitations:

- loft areas have not been accessed other than a general review of the rear section of the main roof from the access hatch.
- The review of floor joists has only been carried out in areas where the floorboards have been lifted.

3.2 Observations and relevant information:

3.2.1 Top floor front room high level water ingress:

Readings through survey locations 6,7,8 & 9 strongly suggest periodic water ingress through the parapet and associated upper wall structures and, corresponding ceiling readings tend to suggest the ingress is limited to the wall structure and not the roof. A similar detail was noted at survey location 11 to the flank wall and in this area, significant cracking was noted to the exterior render to the upper wall. Loss water able to migrate behind

external render systems will, over time, migrate to the interior due the fact the external render and associated decoration greatly reduces, if not prevents the wall venting moisture back to the exterior.

3.2.2 Rear elevation rainwater ingress:

Significant water ingress is occurring in the area of the shoe passing through the parapet wall to the external hopper from the valley gutter behind the parapet. Water ingress in this area may well be a mix of issues affecting the copings, gutter, and shoe detail etc. This area of ingress is significant affecting all the floors down through the structure, saturating the brick elements and driving fungal decay in associated timbers including the stairs etc.

3.2.3 Rear room top floor:

Regarding the rear room adjoining the stairwell, it was noted the exterior wall is dry lined and drilled invasive readings recorded from the masonry indicated elevated moisture readings at survey locations 13 & 14. It is recommended this area is further investigated involving the removal of the dry lining. Issues with upper wall and parapet and or external pointing etc. may well also be allowing rainwater penetration.

3.2.4 First floor flank wall to bathroom:

The moisture survey indicated significantly high moisture in regard to the mortar to the exterior with moderately dry readings to the bricks. A review of the exterior highlighted a significant issue with the pointing to this area of exterior wall which is also influenced by the prevailing weather. Significant rainwater penetration of the exterior wall is indicated and a sample of the affected mortar has been sent for gravimetric analysis.

This will allow a clear understanding of free capillary moisture and/or hygroscopic moisture affecting the mortar with results to follow. Significant rainwater ingress through issues with the window units was also affecting this area.

Gravimetric Analysis - 21st August 2021:

Total moisture content	Hygroscopic moisture	Free capillary moisture		
1.9 %	2.4 %	Nil		

The gravimetric analysis would tend to suggest the mortar was dry at the time of the survey with Hygroscopic salts in the said mortar driving the elevated readings. However, it is the opinion of the author it would be prudent to remediate the exterior wall structure.

3.2.5 Ground floor flank wall entrance:

The exterior wall is saturated generally floor to ceiling and is certainly the case towards the front of the property at survey location 45. Issues with the weather-proofing of the parapet, integrity of the valley gutter etc. may well be allowing the water ingress. This area of the structure has been subject to movement and is also is likely to be a contributory factor.

3.2.6 Previous damp remediation works:

Regarding many of the original wall structures through the ground floor, it was noted the lower wall finishes have been removed and replaced with modern boarding up to the dado rail. As mentioned, the property possibly dates from or before 1820, prior to DPC's being a requirement. The noted boarding is most likely part of remediation carried out in regard to ground moisture affecting the structure and, in a number of areas where boarding was not noted, significant moisture levels to the lower wall was recorded for example survey locations 62 & 64. In the case of the adjoining area survey location 67, elevated resistance readings were recorded in relation to the remediation boarding noted to the lower wall.

3.2.7 Curved exterior walls to rear:

As indicated in the moisture survey, elevated readings were noted at high and low level either side of the patio doors etc. The nature of the wall structure and associated waterproofing to the parapet, is likely to be allowing rainwater penetration to be an issue in regard to the wall structure. In addition, observations noted the roof timber in the area of survey location 93 was saturated as is the floor structure below with significant timber decay noted. This would suggest rainwater ingress through the roof is also an issue in this area.

3.2.8 Older single structures to the rear:

In regard to the single storey slate pitched room areas, significant cracking and deterioration was noted to the render and associated decoration. This, and possible issue with the integrity of the roof structure is allowing rainwater ingress to affect the structure.

3.2.8 Modern flat roof room to the rear:

In a number of areas, the flat roof has failed allowing long term rain ingress to affect the structure. In general wall and floor structure through these areas were saturated.

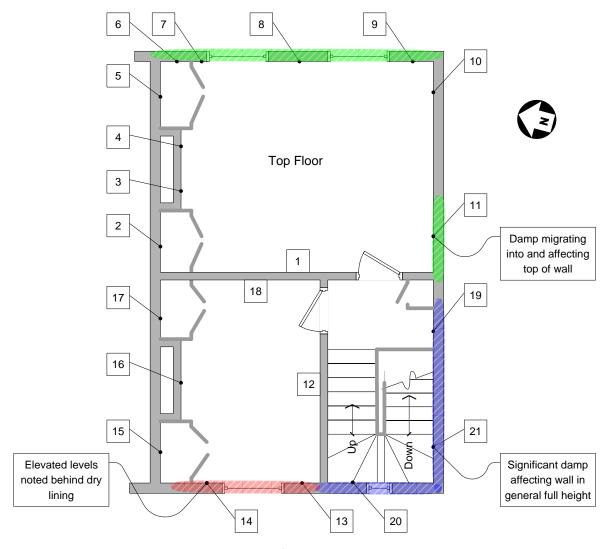

3.2.9 Ground supported concrete slabs:

In a number of areas concrete floor slabs were noted and, due to ongoing rainwater ingress, in general these were saturated. With regard to possible restorative drying, their period and nature of construction would have to be understood to allow drying requirements to be determined.

7.0 Survey Equipment:

Non-destructive moisture readings using:

Protimeter Surveymaster on search mode using radio frequency survey method with readings given numerically from 0 to 999 REL. Survey depth is approximately 5 to 15 mm depending on material characteristics. **Please note** the readings are subjective and open for interpretation, therefore they **should not** be used indicate actual moisture content.

Tramex MRH using electrical impedance survey method on non-wood materials the readings are given numerically from 0 to 99. **Please note** the readings are subjective and open for interpretation, therefore they **should not** be used indicate actual moisture content. Readings taken from wood are given as a %mc the unit can be calibrated to wood species the readings indicated can be taken as an indication of wood moisture content. Survey depth up to 30 mm depending on material characteristics.

Tramex CMEX11 (Concrete encounter meter) using electrical impedance survey method the meter is calibrated to indicate % moisture content by weight in concrete floor slabs and anhydrite screeds.

Invasive moisture readings have been taken using a Protimeter Surveymaster reading direct % moisture in wood and % wood moisture equivalent (%WME) in other materials.

Air moisture readings have been obtained using a Tramex MRH and a Protimeter Hygromaster measuring temperature in °C, % relative humidity and specific moisture content in g/Kg

Note: all readings taken with electronic metering are a guide and should be viewed with all the available information to gauge the true condition. However, for the purposes of this report the following readings can be taken as an indication that the material checked could be said to be dry back to a satisfactory level.
