The ground conditions within the forest are very variable but in principle it comprises a soft layer of organic topsoil and pine needles overlying shale and / or rock

There is a dense population of trees which will be thinned to make space for the log cabins

The remaining tree stumps would, if properly prepared make ideal supports for the log cabins without the need to use piles or construct limecrete posts

Below is a suggested way of forming a platform on which a cabin can be built

Note that the tree stumps are not going to be in a perfect location but it should not matter
